

Adversarial Error Correction

Mayank Mishra (2016EE30506), Tarun Kumar Yadav (2016CS10359), Chahat Chawla (2016MT10492)

Abstract—Deep neural networks have been enormously successful across a variety of classification tasks. However, recent research shows that DNNs are vulnerable to adversarial attacks, which pose a serious threat. In this paper, we propose a simple yet effective defense algorithm Adversarial Error Correction that uses variational autoencoder (VAE) to filter out adversarial noise from input images to a classifier. The proposed method is generic and can defend white-box attacks without the need of retraining the original CNN classifiers, and can further strengthen the defense by.

I. INTRODUCTION

Deep neural networks are highly expressive models that have recently achieved state of the art performance on speech and visual recognition tasks. Despite their ability to learn complicated functions, little is known about what they learn. Deep neural networks learn input-output mappings that are fairly discontinuous to a significant extent. We can cause the network to misclassify an image by applying a certain hardly perceptible perturbation, which is found by maximizing the network's prediction error. In addition, the specific nature of these perturbations is not a random artifact of learning: the same perturbation can cause a different network, that was trained on a different subset of the dataset, to misclassify the same input.

Machine learning models are vulnerable to these small perturbations. Such examples with these perturbations are called adversarial examples. These adversarial examples look similar to their non-adversarial counterparts but lead to poor classification accuracy of deep learning systems on a particular task.

II. ADVERSARIAL ATTACKS

A. Fast Gradient Sign Method (FGSM)

FGSM[1] is a single step attack. Let $L(\mathbf{x}, \mathbf{y})$ be the loss function of the classifier C given input \mathbf{x} and label \mathbf{y} . FGSM defines the perturbation $\boldsymbol{\rho}$ as

$$\boldsymbol{\rho} = \epsilon \times \text{sign}(\nabla_{\mathbf{x}} L(\mathbf{x}, \mathbf{y})) \quad (1)$$

where ϵ is a small factor. FGSM simply chooses the sign of change at each pixel to increase the loss $L(\mathbf{x}, \mathbf{y})$ and fool the classifier.

B. Projected Gradient Descent

PGD[2] is a more powerful multi-step attack with projected gradient descent.

$$\begin{aligned} \mathbf{x}_0^{PGD} &= \mathbf{x} \\ \mathbf{x}_{t+1}^{PGD} &= \prod_S [\mathbf{x}_t^{PGD} + \alpha \times \text{sign}(\nabla_{\mathbf{x}} L(\mathbf{x}_t^{PGD}, \mathbf{y}))] \end{aligned} \quad (2)$$

where \prod_S is the projection onto $S = \{\mathbf{x}' : \|\mathbf{x}' - \mathbf{x}\|_{\infty} \leq \epsilon\}$.

III. VARIATIONAL AUTOENCODERS

Generative models have gained a lot of success since the advent of deep neural networks. In particular, GANs[3] and VAEs[4] have been used to model highly complex distributions whose implicit expressions might be intractable. It can be easily shown that the log likelihood of the data can be written as

$$\log p(\mathbf{x}) \geq -KL[q_{\phi}(\mathbf{z}|\mathbf{x})||p_{\theta}(\mathbf{z})] + \mathbb{E}_{q_{\phi}(\mathbf{z}|\mathbf{x})}[\log p_{\theta}(\mathbf{x}|\mathbf{z})] \quad (3)$$

To achieve the goal maximizing the log-likelihood, one can simply maximize a lower bound, evidence lower bound (ELBO) on the log-likelihood. This can be done by using a VAE.

IV. EXPERIMENTS AND RESULTS

A. Datasets

For the purpose of this paper, we experimented on the Fashion MNIST dataset (black and white images of the dimension 28×28) and the SVHN dataset (coloured images of the dimension 32×32). Both datasets have 10 ground truth classes.

B. Adversarial attacks

We perform the two mentioned adversarial attacks in this paper i.e FGSM[1] and PGD[2]. The resulting images generated using FGSM for Fashion MNIST are shown in Fig. 1. The resulting images generated using PGD for Fashion MNIST are shown in Fig. 2 and for SVHN in Fig. 3.

C. Defense mechanisms

We try out two defense mechanisms to protect our classifiers as discussed below:

1) *Adversarial retraining*: We do adversarial retraining of the classifiers. Basically, in this approach the classifier are retrained on the adversarial examples.

2) *Adversarial error correction*: In this approach the adversarial examples are passed through a VAE whose encoder is K-Lipschitz. The claim is that if the encoder is K-Lipschitz the adversarial examples and the real examples would be close enough in the latent space. This Lipschitz constraint on the encoder is imposed by having a gradient penalty on the encoder.

D. Further studies

It is further seen that as the dimensionality of the latent space is increased the adversarial examples and the real data come closer in the latent space. (See Fig. 4)

TABLE I: Accuracy on Fashion MNIST with and without defense mechanisms

Attack	No defense	Adversarial retraining			Adversarial error correction
		FGSM 0.3	PGD 0.1	PGD 0.3	VAE
No attack	91.2	91.4	89.9	91	82.2
FGSM ($\epsilon = 0.1$)	24.2	82.6	81	75.9	62.7
FGSM ($\epsilon = 0.3$)	9.1	89.4	42.4	74.4	49.2
PGD ($\epsilon = 0.1$)	5.9	12.1	71.7	61.8	50.5
PGD ($\epsilon = 0.3$)	5.7	5.6	7.1	68.1	44.2

TABLE II: Accuracy on SVHN with and without defense mechanisms

Attack	No defense	Adversarial error correction
		VAE
No attack	93.7	83.4
FGSM ($\epsilon = 0.05$)	11.4	66.4
FGSM ($\epsilon = 0.1$)	10.8	47.7
PGD ($\epsilon = 0.05$)	3.4	71.5
PGD ($\epsilon = 0.1$)	2.9	60.9

V. CONCLUSION

In this paper, we have proposed a simple yet effective defense algorithm Adversarial Error Correction that uses a variational autoencoder (VAE) to filter out adversarial noise from input images to a classifier. The proposed method is generic and can defend white-box attacks without the need of retraining the original classifiers, and can further strengthen the defense.
